**Milestone 4**: SARSA would be more conservative because it make safe decisions accounting for possible agent mistakes and follow an epsilon greedy policy where according to the epsilon vlaue it both explores and exploits so its overall rewards would be slightly lower than Q-learning, which is an off-policy algorithm and takes more risks and chooses the maximum reward action at all steps.

What was actually observed: FastGrasp was used by SARSA, which means it chose to take riskier actions regardless of the fact that the wear = 8, which did not match the prediction by intuition. FastGrasp was used also by Q-learning. The FastGrasp being used by SARSA at wear = 8 also matches up with the fast advantage png that we generated from the algorithms earlier. Until around wear = 9, the advantage for SARSA using FastGrasp does not seem to decline. After which, it sharply declines to preferring SlowGrasp.
